

POSITIONING SYSTEM AND
EXPOSURE APPARATUS HAVING THE SAME

FIELD OF THE INVENTION AND RELATED ART

5 This invention relates to a positioning
system suitably usable in high precision
processing such as semiconductor lithography, for
example, and an exposure apparatus having such a
positioning system. In another aspect, the
10 invention concerns a device manufacturing method
using such exposure apparatus.

 Typical exposure apparatuses for
manufacture of semiconductor devices include a
step-and-repeat type exposure apparatus (called a
15 "stepper") in which a pattern of an original
(reticle or mask) is sequentially transferred to
plural exposure regions on a substrate (wafer or
glass substrate) through a projection optical
system while the substrate is moved stepwise, and
20 a step-and-scan type exposure apparatus (called a
"scanner") in which, by repeating stepwise motion
and scan exposure, exposure and transfer are
carried out repeatedly to plural regions on a
substrate.

25 Particularly, the step-and-scan type
apparatuses use only a portion relatively close to
the optical axis of a projection optical system

with the restriction by a slit, and therefore it enables higher precision and wider picture angle exposure of a fine pattern. Such exposure apparatuses generally comprise a positioning stage system (wafer stage or reticle stage) for moving a wafer or reticle at a high speed and then positioning the same, as disclosed in Japanese Laid-Open Patent Application No.62-88526, for example.

10

SUMMARY OF THE INVENTION

Japanese Laid-Open Patent Application No.62-88526 discloses a structure that the driving position of an X-Y movable guide and the gravity center position of a stage are at the same level thereby to prevent yawing and pitching of the stage. However, in such stage system, there is no reaction force absorbing mechanism for absorbing a propulsion reaction force to be produced by motion of a movable portion. Therefore, when the stage is driven, a reaction force of inertia is produced as a result of acceleration or deceleration. If it is transmitted to a base table, it causes swinging motion or vibration of the base table. Hence, the natural vibration of the mechanism system of the exposure apparatus may be excited by swinging motion or vibration of the base table to

generate high frequency vibration. This is a factor that obstructs high-speed motion and high-precision positioning.

It is accordingly an object of the
5 present invention to provide a positioning system by which vibration or swinging motion resulting from stage motion can be reduced such that high-speed and high-precision positioning can be accomplished. Also, it is an object of the
10 present invention to provide an exposure apparatus, for example, in which such a positioning system is incorporated. Particularly, it is an object of the present invention to reduce vibration or swinging motion of a base table to be produced by
15 a moment reaction force, resulting from motion of a stage.

In accordance with an aspect of the present invention, to achieve at least one of the objects described above, there is provided a
20 positioning system, comprising: a movable portion supported for movement along a reference plane; a reaction force absorbing mechanism for absorbing a propulsion reaction force to be produced by motion of said movable portion; and a motor movable
25 element for propelling said movable portion along the reference plane, wherein a first distance between the reference plane and a gravity center

position of said movable portion and a second distance between the reference plane and a gravity center position of said reaction force absorbing mechanism are made substantially equal to each other and/or the second distance and a third distance between the reference plane and said motor movable element are made substantially equal to each other.

In one preferred form of this aspect of the present invention, said reaction force absorbing mechanism comprises a stator of a motor for driving said movable portion.

The reaction force absorbing mechanism may be adapted to move the reference plane.

In accordance with another aspect of the present invention, there is provided a positioning system, comprising: a movable portion supported for movement in two axial directions being substantially orthogonal to each other along a reference plane; an X movable member including said movable portion; a Y movable member including said movable portion; a first reaction force absorbing mechanism for absorbing a propulsion reaction force to be produced by motion of said X movable member in a first movement direction; and a second reaction force absorbing mechanism for absorbing a propulsion reaction force to be

produced by motion of said Y movable member in a second movement direction, wherein a fourth distance between the reference plane and a gravity center position of said X movable member and a fifth distance between the reference plane and a gravity center position of said first reaction force absorbing mechanism are made substantially equal to each other, and a sixth distance between the reference plane and a gravity center position of said Y movable member and a seventh distance between the reference plane and a gravity center position of said second reaction force absorbing mechanism are made substantially equal to each other.

In one preferred form of this aspect of the present invention, said X movable member includes a first beam member for transmitting, to said movable portion, a propulsion force for propelling said movable portion in a first direction, and a first motor movable element for propelling said movable portion in the first direction.

The Y movable member may include a second beam member for transmitting, to said movable portion, a propulsion force for propelling said movable portion in a second direction, and a second motor movable element for propelling said

movable portion in the second direction.

The X movable member may include said movable portion, a second movable portion provided on said movable portion, a first beam member for transmitting, to said movable portion, a propulsion force for propelling said movable portion in a first direction, and a first motor movable element for propelling said movable portion in the first direction.

The Y movable member may include said movable portion, a second movable portion provided on said movable portion, a second beam member for transmitting, to said movable portion, a propulsion force for propelling said movable portion in a second direction, and a second motor movable element for propelling said movable portion in the second direction.

The second movable portion may comprise a fine-motion stage for adjusting a position and an attitude of said movable portion.

In accordance with a further aspect of the present invention, there is provided a positioning system, comprising: a movable portion supported for movement in two axial directions being substantially orthogonal to each other along a reference plane; a first guide member for guiding said movable portion in a first direction;

a second guide member for guiding said movable portion in a second direction; a first reaction force absorbing mechanism for absorbing a propulsion reaction force to be produced by motion of said movable portion in a first direction; and a second reaction force absorbing mechanism for absorbing a propulsion reaction force to be produced by motion of said movable portion in a second direction, wherein an eighth distance between the reference plane and a gravity center position of said first guide member and a ninth distance between the reference plane and a gravity center position of said first reaction force absorbing mechanism are made substantially equal to each other, and a tenth distance between the reference plane and a gravity center position of said second guide member and an eleventh distance between the reference plane and a gravity center position of said second reaction force absorbing mechanism are made substantially equal to each other.

In accordance with a yet further aspect of the present invention, there is provided a positioning system, comprising: a movable portion supported for movement in two axial directions being substantially orthogonal to each other along a reference plane; a first motor movable element

for propelling said movable portion in a first direction along the reference plane; a second motor movable element for propelling said movable portion in a second direction along the reference plane; a first reaction force absorbing mechanism for absorbing a propulsion reaction force to be produced by motion of said movable portion in the first direction; and a second reaction force absorbing mechanism for absorbing a propulsion reaction force to be produced by motion of said movable portion in the second direction, wherein a twelfth distance between the reference plane and a gravity center position of said first motor movable element and a thirteenth distance between the reference plane and a gravity center position of said first reaction force absorbing mechanism are made substantially equal to each other, and a fourteenth distance between the reference plane and a gravity center position of said second motor movable element and a fifteenth distance between the reference plane and a gravity center position of said second reaction force absorbing mechanism are made substantially equal to each other.

In accordance with a still further aspect of the present invention, there is provided a positioning system, comprising: a movable portion supported for movement in two axial

directions being substantially orthogonal to each other along a reference plane; a first guide member for guiding said movable portion in a first direction; and a first motor movable element for propelling said movable portion in a first direction along the reference plane, wherein an eighth distance between the reference plane and a gravity center position of said first guide member and a twelfth distance between the reference plane and said first motor movable element are made substantially equal to each other.

In accordance with a still further aspect of the present invention, there is provided a positioning system, comprising: a movable portion supported for movement in two axial directions being substantially orthogonal to each other along a reference plane; a second guide member for guiding said movable portion in a second direction; and a second motor movable element for propelling said movable portion in a second direction along the reference plane, wherein a tenth distance between the reference plane and a gravity center position of said second guide member and a fourteenth distance between the reference plane and said second motor movable element are made substantially equal to each other.

At least one of said first guide member

and said second guide member may include a plurality of guiding elements spaced from each other with respect to a direction of the reference plane.

5 The first and second reaction force absorbing mechanisms may include a stator of a motor for driving said movable portion.

 In accordance with another aspect of the present invention, there is provided an
10 exposure apparatus, comprising: an original positioning system for holding an original and for moving the original to a predetermined position and positioning the same at the predetermined position; a substrate positioning system for
15 holding a substrate and for moving the substrate to a predetermined position and positioning the same at the predetermined position; and a projection optical system for projecting a pattern of the original onto the substrate, wherein at
20 least one of said original positioning system and said substrate positioning system comprises a positioning system as recited above.

 In accordance with a yet further aspect of the present invention, there is provided a
25 device manufacturing method, comprising the steps of: applying a photosensitive agent to a substrate; exposing the substrate by use of an

exposure apparatus as recited above; and
developing the exposed substrate.

These and other objects, features and
advantages of the present invention will become
5 more apparent upon a consideration of the
following description of the preferred embodiments
of the present invention taken in conjunction with
the accompanying drawings.

10 BRIEF DESCRIPTION OF THE DRAWINGS

Figures 1A and 1B are schematic views,
respectively, for explaining the structure of a
positioning system according to a first embodiment
of the present invention.

15 Figures 2A and 2B are schematic views,
respectively, for explaining the structure of a
positioning system according to a second
embodiment of the present invention.

Figure 3 is a schematic view for
20 explaining the structure of a positioning system
according to a third embodiment of the present
invention.

Figure 4 is a schematic view for
explaining a moment reaction force resulting from
25 misregistration of a gravity center position.

Figure 5 is a schematic view for
explaining a general structure of an exposure

apparatus to which a positioning system according to an embodiment of the present invention is incorporated.

Figure 6 is a flow chart for explaining a general procedure for manufacture of semiconductor devices.

Figure 7 is a flow chart for explaining details of a wafer process, included in the flow chart of Figure 6.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Preferred embodiments of the present invention will now be described with reference to the attached drawings.

[First Embodiment]

Structure of Positioning System:

Figures 1A and 1B are schematic views, respectively, for explaining the structure of a positioning system according to a first embodiment of the present invention. In the drawings, denoted at 1 is a movable table, and denoted at 2 and 2' are Y linear motor movable elements for moving the movable table 1 in a Y-axis direction. Denoted at 3 and 3' are Y linear motor stators. Denoted at 4 is a stage base (base table) having a guide surface at its top face on which a movable

table 1 and the Y linear motor stators 3 and 3' and so on are mounted. Denoted at 5 and 5' are Y yawing guides for restricting yawing of the Y linear motor stators (eccentric swinging motion or run of the Y linear motor stators 3 and 3').

Denoted at 6 and 6' and 7 and 7' are static bearings adapted to float the side and bottom faces of the Y linear motor stators 3 and 3' and the bottom face of the movable table 1, respectively, by static pneumatic pressure.

The movable table 1 is supported by the static bearing 8 with respect to the stage base 4 without contact thereto as seen in Figure 1B, and it is movable in Y direction. Fixedly mounted at the opposite sides of the movable table 1 are the Y linear motor stators 2 and 2' for driving the movable table 1 in Y direction. As shown in Figure 1B, each of the Y linear motor stators 2 and 2' is movably accommodated inside a recessed portion of the Y linear motor stator 3 or 3', with a predetermined clearance maintained therebetween.

More specifically, the Y linear motor stators 3 and 3' are supported by the static bearings 7 and 7' with respect to the stage base 4, without contact thereto, and simultaneously it is supported by the static bearings 6 and 6' with respect to the Y yawing guides 5 and 5' without

contact thereto, while the stators 3 and 3' are movable along the Y direction. Further, these Y linear motor stators 3 and 3' have a predetermined mass so that they can function as a reaction force counter, to be described later.

The Y linear motor movable elements 2 and 2' are connected to the movable table 1, such that, with the motion of the movable elements, the movable table 1 moves in Y direction. At this time, a reaction force of driving force (drive reaction force) is produced by the motion of the movable table 1, and it is applied to the Y linear motor stators 3 and 3'. Since the Y linear motor stators 3 are supported for movement upon the stage base 4, with the driving reaction force the Y linear motor stators move along the stage base 4 in a direction opposite to the movement direction of the movable table 1.

Hence, through the movement of the Y linear motor stators 3 and 3' along the stage base 4, transmission of the drive reaction force to the stage base 4 can be prevented effectively. Thus, the Y linear motor stators 3 and 3' function as a reaction force counter.

In this embodiment, if the movable table 1 moves in a positive Y direction, for example, the Y linear motor stators 3 and 3'

receive a drive reaction force in a negative Y direction, such that, with this negative-direction force as a driving force, the stators 3 and 3' are moved in the negative Y direction.

5 The positioning system may be provided with one or more laser interferometers (not shown) for positioning the movable table with respect to a predetermined position, and, through a position control based on positional information obtained
10 by the laser interferometers, the movable table 1 may be positioned. Similarly, the position of the stators may be measured by use of unshown interferometers thereby to position the Y linear motor stators 3 and 3' which are a reaction force
15 counter moving along a plane.

 With the structure shown in Figures 1A and 1B, the reaction force during acceleration and deceleration of the movement of the movable table 1 is received by the Y linear motor stators 3 and
20 3' (serving as a reaction force counter), and through the motion of the Y linear motor stators 3 and 3', the drive reaction force is converted into kinetic energy of the stators 3 and 3'. As a
result of this, vibration of the stage base 4 due
25 to the drive reaction force resulting from the motion of the movable table 1 can be prevented effectively. In addition, transmission of

vibration to the floor surface where the apparatus having the positioning system incorporated therein is mounted can be prevented effectively.

Therefore, the positioning system excludes factors
5 that cause external disturbance (vibration source) not only with respect to the machine in which the system itself is incorporated but also with respect to another machine.

Further, since the Y linear motor
10 stators 3 and 3' move along the stage base 4 in accordance with acceleration of the movable table 1, any offset load during the motion of the movable table 1 can be made small. As a result, for holding and positioning a wafer, for example,
15 uniform position and attitude can be accomplished throughout the entire movement range of the movable table. For wafer exposure, the overlay precision is improved significantly. In accordance with the present embodiment, since the
20 Y linear motor stators 3 and 3' move in a direction opposite to the movement direction of the movable table 1, any change in gravity center position of the whole structure, including the movable table 1 and the stators 3 and 3', can be
25 suppressed significantly. Therefore, even with the motion of the movable table 1, the load balance upon the stage base 4 does not change

largely and, as a result of it, the offset load due to the motion of the movable table 1 can be made small.

Furthermore, in accordance with the present embodiment, the linear motor stators 3 and 3' are provided independently of each other. As a result, even if the forces applied to the Y linear motor movable elements 2 and 2' are different, the reaction force can be cancelled through separate movements of the Y linear motor stators 3 and 3'. For example, if the movable table 1 is moved rotationally in θ direction or where a certain object placed on the movable table 1 has an offset load with respect to X direction, outputs of the Y linear motor movable elements 2 and 2' may be different. Even in such case, however, since the Y linear motor stators 3 and 3' can be moved separately, effective cancellation of the drive reaction force is accomplished.

With the structure such as shown in Figures 1A and 1B, the drive reaction force to be produced by acceleration or deceleration of the movable table 1 can be converted into kinetic energies through the movements of the Y linear motor stators 3 and 3' in opposite directions, and thus it can be absorbed thereby. In this manner, swinging motion or vibration of the base table due

to the drive reaction force can be avoided or suppressed effectively.

Absorption of Moment about Gravity Center:

5 If, however, there is misregistration between the gravity center level (height) and of the movable table 1 and the gravity center level of the stator Y linear motor, it is necessary to take into account the moment about the gravity
10 center of the structure, including the stage base. More specifically, the moment about the X-axis to be applied to the apparatus as a whole due to the motion of the movable table 1 and the moment about the X-axis to be applied to the apparatus as a
15 whole due to the movement of the Y linear motor stators 2 and 2' do not balance with each other, such that a moment corresponding to the difference therebetween is applied to the stage base consequently.

20 For example, as shown in Figure 4, where the gravity center position G1 of the movable table 1 (the height in Z direction, taking the top face of the stage base 4 as a reference) is higher than the gravity center position G2 of
25 the Y linear motor stators 3 and 3', if the movable table 1 is moved in positive Y direction (leftward in Figure 4), a clockwise moment in

negative ωx direction (moment reaction force) is applied to the stage base as a result of it.

On the other hand, since the Y linear motor stators 3 and 3' move in negative Y direction in response to application of a drive reaction force in negative Y direction thereto, as a result a counterclockwise moment in positive ωx direction (moment reaction force) is applied to the stage base 4.

Obviously, if the applied forces are equal to each other, the former moment having a higher gravity center is larger. As a consequence, therefore, the moment in negative ωx direction is dominantly applied to the stage base. Where the gravity center positions are different as described above, the moment reaction force could not be cancelled with the structure of the Y linear motor stators 3 and 3'. As a result, the vibration of the stage base 4 is accelerated by the moment reaction force, while vibration of the floor where the apparatus is mounted is excited. Hence, vibration of the machine itself as well as vibration of another machine may be excited.

In the structure of the positioning system according to the present embodiment, as shown in Figures 1A and 1B, in order to extinguish the adverse influence of the moment reaction force

such as described with reference to Figure 4, the gravity center position of the Y linear motor stators 3 and 3' and the gravity center position (G1) of the whole moving structure, including the movable table 1 and the Y linear motor movable elements 2 and 2', are set at the same level (height). With this arrangement, the drive reaction force to be produced by the motion of the movable table 1, as well as the moment reaction force to be applied to the stage base, can be cancelled completely.

Line of Action of the Linear Motor:

In the present embodiment, as shown in Figure 1B, preferably the height (G3) of the line of action of the force to be applied to the Y linear motor movable elements is set at the same level as the height (G2) of the gravity center position of the Y linear motor stators 3 and 3'. With this arrangement, the Y linear motor propulsion force can be applied to the gravity center height of the Y linear motor stators 3 and 3'. Thus, regarding the operation of the Y linear motor stators 3 and 3' as a single unit, it does not produce a moment about the gravity center thereof. Hence, there is an advantage that excitation of vibration to the stage base 4 can be

avoided. Simultaneously, the Y linear motor propulsion force acts on the gravity center height (G1) of the movable table 1 or on the gravity center height of the whole movement structure, including the movable table 1 and the Y linear motor movable elements 2 and 2'. Therefore, regarding the operation of the movable table 1 or the operation of only the whole movement structure including the movable table 1 and the Y linear motor movable elements 2 and 2', it does not produce a moment about the gravity center thereof. Hence, excitation of vibration to the stage base can be prevented effectively.

With the structure described above, the drive reaction force in the Y-axis direction which is the movement direction of the movable table 1 is absorbed by the motion of the stators. Further, the gravity center height (G1) of the movable table 1, the gravity center height (G2) of the linear motor stators 3 and 3', and the height (G3) of the line of action of the linear motor are registered with each other, by which production of moment reaction force about the Z axis can be prevented. As a result, a high-speed and high-precision positioning system in which excitation of vibration or swinging motion of the stage base is prevented, is accomplished.

While the present embodiment has been described with reference to an example wherein the guide surface of the movable table 1 and the guide surface of the Y linear motor stators 3 and 3' are
5 coplanar (i.e. stage base 4), they may be defined upon different parallel planes, and substantially the same advantageous effects are attainable in that occasion.

10 [Second Embodiment]

Figures 2A and 2B illustrate the structure of a positioning system according to a second embodiment of the present invention. Figure 2A is a plan view of the positioning system,
15 and Figure 2B is a front view thereof. In these drawings, those elements corresponding to the components of Figures 1A and 1B are denoted by like numerals. Denoted at 9 is a fine-motion table which is mounted on a movable table 1 and
20 which can operate to perform upward and downward motion and tilt motion. Denoted at 10 is a reflection mirror mounted on the fine-motion table 9. Denoted at 11 is a plurality of fine-motion actuators which are provided on the movable table
25 1 and which function to perform upward and downward motion and tilt motion of the fine-motion table.

Denoted at 12 is an X beam (beam member) for moving the movable table 1 in X-axis direction. Denoted at 13 is a Y beam for moving the movable table 1 in Y direction. Formed on the opposite side faces 12a and 12b of the X beam 12 are Y guide surfaces for guiding the motion of the movable table 1 in the Y direction. Also, formed on the opposite side faces 13a and 13b of the Y beam 13 are X guide surfaces for guiding the motion of the movable table 1 in the X direction. There are a plurality of static bearings (not shown) which are provided between the movable table 1 and the Y guide surfaces, formed on the X beam 12, and the X guide surfaces, formed on the Y beam 13. Hence, non-contact force transmission and straight guiding operation are carried out thereby.

Denoted at 14 and 14' are Y sliders disposed at the opposite ends of the Y beam 13. Denoted at 15 and 15' are static bearings provided at the bottom faces of the Y sliders. Similarly, denoted at 16 and 16' are X sliders disposed at the opposite ends of the X beam 12. There are similar static pads disposed at the bottom faces of the X sliders, while not shown in the drawings.

Denoted at 17 and 17' are X linear motor movable elements for moving the X beam 12 in

X direction. Denoted at 18 and 18' are X linear motor stators. Denoted at 20 and 20' are X yaw guides for restricting yawing motion of the X linear motor stators 18 and 18'. Also, denoted at 5 19 and 19' are static bearings for floating the side faces of the X linear motor stators 18 and 18' through static pneumatic pressure. Similar static bearings are provided at the bottom faces, while not shown in the drawing.

10 The movable table 1 is supported by the static bearings 8 with respect to the stage base 4 without contact thereto, as shown in Figure 2B, and it can be moved in X and Y directions. The movable table 1 has the X beam 12 and Y beam 13 15 extending therethrough, substantially orthogonally to each other. There are static bearings (not shown) at the opposed faces of the Y guide surfaces of the X beam 12 and the X guide surface of the Y beam 13, of the movable table 12, which 20 bearings function to perform transmission of forces and various drive-guiding operations. As a result, the movable table 1 can always be positioned at the point of intersection between the X and Y beams.

25 The X sliders 16 and 16' and the Y sliders 14 and 14' are coupled to the opposite ends of the X beam 12 and the Y beam 13,

respectively. Also, there are static bearings mounted at the bottom faces of the sliders. As a result, a combined structure of the X beam 12 and the X sliders 16 and 16' is movable in X direction, and a combined structure of the Y beam 13 and the Y sliders 14 and 14' are movable in Y direction, as seen in Figure 2B.

The X linear motor movable elements 17 and 17' and the Y linear motor movable elements 2 and 2' are coupled to the X sliders 16 and 16' and the Y sliders 14 and 14', respectively, such that these sliders can be driven by propulsion forces produced by these linear motors, respectively. The X linear motor movable elements 17 and 17' and the Y linear motor movable elements have the X linear motor stators 18 and 18' and the Y linear motor stators 3 and 3' disposed opposed to each other. The linear motor structures in the respective movement directions are provided, in the manner described above.

Here, the X linear motor stators 18 and 18' and the Y linear motor stators 3 and 3' are supported by the static bearings 7 and 7' (those at the X linear motor side are unshown) with respect to the stage base 4 without contact thereto. Simultaneously, they are supported by static bearings 19, 19' and 6 and 6' with respect

to the X yawing guides 20 and 20' and Y yawing guides 5 and 5', without contact thereto. Thus, they are movable along the X and Y directions.

5 Absorption of Drive Reaction Force:

The X linear motor stators 18 and 18' and the Y linear motor stators 3 and 3' have predetermined masses, respectively, and they serve as a reaction force counter, like the first
10 embodiment. The X linear motor movable elements 17 and 17' and the Y linear motor movable elements 2 and 2' are connected to the X sliders 16 and 16' and the Y sliders 14 and 14', respectively, and they are movable in X and Y directions,
15 respectively. In turn, the X sliders 16 and 16' and the Y sliders 14 and 14' are connected to the X beam 12 and the Y beam 13, respectively. Thus, through the motion of the beams in X and Y direction, the movable table 1 placed at the
20 intersection of the beams is driven in X and Y directions.

When the movable table 1 is driven in X or Y direction in response to the propulsion force of a corresponding linear motor, a drive reaction
25 force which acts on in the motion of the movable table 1 in X or Y direction is applied to the X linear motor stators 18 and 18' or the Y linear

motor stators 3 and 3'.

With this drive reaction force, the X linear motor stators 18 and 18' or the Y linear motor stators 3 and 3' can move along the stage base 4 surface, in X or Y direction which is opposite to the movement direction of the movable table 1. Through the motion of the X linear motor stators 18 and 18' and the Y linear motor stators 3 and 3' in X and Y directions along the stage base 4 surface, the drive reaction force is converted into kinetic energies of the stators, such that the drive reaction force can be cancelled thereby. Therefore, transmission of the drive reaction force to the stage base 4 can be prevented effectively, and so the linear motor stators 3 and 3' and 18 and 18' can serve as a reaction force counter.

If for example the movable table 1 is moved in positive X direction, the X linear motor stators 18 and 18' move in negative X direction in response to application of the drive reaction force thereto in the negative X direction. If the movable table 1 moves in positive Y direction, the Y linear motor stators 3 and 3' are moved in negative Y direction in response to application of the drive reaction force thereto in the negative Y direction.

Absorption of Moment about Gravity Center:

However, the influence of moment due to misregistration of a gravity center height of the whole structure, including a movable table and a combination of it, for example, as has been described with reference to the first embodiment, is similarly a problem to be considered. For example, where the movable table 1 moves in X direction, if the general gravity center height of the whole movement structure (hereinafter, X-direction movement structure), including the movable table 1, the fine-motion table 9, the reflection mirror 10, the fine-motion actuators 11, the X beam 12, the X sliders 16 and 16', and the X linear motor movable elements 17 and 17', is not registered with the gravity center height of the X linear motor stators 18 and 18', the moment reaction force about the Y axis can not be cancelled. As a result, vibration of the stage base 4 is accelerated by the moment reaction force about the Y axis and, finally, vibration of the floor where the machine is mounted may be excited. This leads to factors (vibration source) for causing external disturbance to the machine itself and also to another machine.

Similarly, where the table is moved in

Y direction, if the general gravity center height of the whole movement structure (hereinafter, Y-direction movement structure), including the movable table 1, the fine-motion table 9, the reflection mirror 10, the fine-motion actuators 11, the Y beam 13, the Y sliders 14 and 14', and the Y linear motor movable elements 2 and 2', is not registered with the gravity center height of the Y linear motor stators 18 and 18', the moment reaction force about the X axis can not be cancelled and vibration of the stage base 4 is accelerated thereby.

In accordance with the present embodiment, in order to cancel the influence of the moment reaction force such as described above, the gravity center height of the X-direction movement structure and the gravity center height of the X linear motor stators 18 and 18' are made substantially at the same level. Also, the gravity center height of the Y-direction movement structure and the gravity center height of the Y linear motor stators 18 and 18' are made substantially at the same level. With this arrangement, the drive reaction force to be produced by the motion of the movable table 1 as well as the moment reaction force to be applied to the stage base 4 can be cancelled completely.

Furthermore, in this embodiment, preferably, the gravity center height of a movement structure (hereinafter, unit X-axis movement structure), including the X beam 12, the X sliders 16 and 16', and the X linear motor movable elements 17 and 17', and the gravity center height of a movement structure (hereinafter, unit Y-axis movement structure), including the Y beam 13, the Y sliders 14 and 14', and the Y linear motor movable elements 2 and 2', are made at the same level. Also, the gravity center heights of the X-linear motor stators 18 and 18' and of the Y linear motor stators 3 and 3' are preferably made at the same level. With this arrangement, even in respect to the action-reaction interrelationship between the linear motor stators and unit X-axis and Y-axis movement structures, there does not occur a moment about the X axis or Y axis with respect to the stage base 4, such that excitation of vibration of the stage base can be avoided.

Line of Action of Linear Motor:

Further, in the present embodiment, as shown in Figures 1A and 1B, preferably, the line of action of the force to be applied to the linear motor movable elements is made at the same level

as the gravity center height of the linear motor
stators. With this structure, the linear motor
propulsion force acts on at the gravity center
height of the linear motor stators. Thus, even
5 regarding the operation of the X linear motor
stators 18 and 18' and the Y liner motor stators 3
and 3' as a unit, it does not produce a moment
about the gravity center thereof. As a result,
excitation of vibration to the stage base 4 can be
10 avoided.

In accordance with the structure
described above, a stage system in which not only
a reaction force in X-axis or Y-axis direction
which is the movement direction of the movable
15 table 1 but also a moment in X-axis, Y-axis or Z-
axis direction, are never produced to the stage
base, can be accomplished as a consequence.

In the structure described above, the
drive reaction force to be produced by the motion
20 of the movable table 1 is absorbed by the movement
of the stators. Additionally, the gravity center
height of the movement structure, the gravity
center height of the linear motor stators, and the
height of the linear motor action line (G3) are
25 made at the same level. This effectively prevents
production of a moment reaction force about the Z
axis. Thus, a positioning system in which

swinging motion or vibration of the stage base 4 is not excited, can be accomplished.

Although the present embodiment has been described with reference to an example
5 wherein the guide surface of the movable table 1 and the guide surface of the Y linear motor stators 3 and 3' are coplanar (i.e. stage base 4), they may be defined upon different parallel planes, and substantially the same advantageous effects
10 are attainable in that occasion.

[Third Embodiment]

Figure 3 is a front view for explaining the structure of a positioning system according to
15 a third embodiment of the present invention. The top view of the same may be similar to the top view of Figure 2A. In Figure 3, those components corresponding to the elements of Figures 1 and 2 are denoted by like numerals. This embodiment
20 differs from the second embodiment in that the Y beam comprises two, that is, upper and lower beams. More specifically, denoted at 130a and 130b are Y beams having two, upper and lower beams. X guide surfaces for guiding the motion of the movable
25 table 1 in X direction are defined at the opposite side faces of these Y beams, respectively. There are static bearings (not shown) disposed between

the movable table 1 and these guide surfaces, such that non-contact and straight motion guiding operation is carried out.

In this embodiment, the X beam 12
5 comprises a single beam while the Y beam comprises two beams 130a and 130b disposed in vertical direction. This facilitates easy designing for providing a structure in which the gravity center height of a unit X-axis movement structure,
10 including the X beam 12, the X sliders 16 and 16' and the X linear motor movable elements 17 and 17', and the gravity center height of the unit Y-axis movement structure, including the Y beams 130a and 130b, the Y sliders 14 and 14', and the Y linear
15 motor movable elements 2 and 2', are made substantially at the same level.

Alternatively, since in this embodiment the X beam 12 comprises a single beam while the Y beam comprises two beams 130a and 130b disposed in
20 vertical direction, the gravity center height of the Y guide surfaces formed at the side faces of the X beam 12 and the gravity center height of the X guide surfaces defined at the side faces of the Y beams 130a and 130b, can be made at the same
25 level. The gravity center height of these X and Y guide surfaces corresponds to the height of the line of action of the force as the X-direction and

Y-direction driving forces of the X beam 12 and Y beams 130a and 130b are transmitted to the movable table 1. Any difference between the gravity center height of the movable table 1 and the gravity center height of the guide surfaces corresponds to the moment to be applied to the movable table 1.

Hence, since the gravity center height of the Y guide surfaces 12a and 12b defined at the side faces of the X beam 12 is at the same level as the gravity center height of the X guide surfaces formed at the side faces of the Y beam 130a and 130b, the moments to be applied by the X-direction motion and Y-direction motion of the movable table 1 are equal to each other. As a result, dynamic actions such as vibration convergence time or largest pitching amount can be made approximately equal to each other.

Further, the gravity center height of the X guide surfaces and Y guide surfaces is made substantially at the same level as the gravity center height of the whole movement structure, including the movable table 1, the fine-motion table 9, the reflection mirror 11, and the fine-motion actuators 11, and, in this arrangement, the transmission force of the propulsion force of each linear motor can act on to the gravity center of

the whole movement structure. As a result, a moment about the gravity center is not produced, and excitation of vibration to the stage base 1 can be avoided.

5 Preferably, the gravity center height of the X movement structure, including the X beam 12, the X sliders 16 and 16' and the X linear motor movable elements 17 and 17', and the gravity center height of the Y movement structure,
10 including the Y beams 130a and 130b, the Y sliders 14 and 14', and the Y linear motor movable elements 2 and 2', as well as the lines of action of the propulsion forces of the linear motor
15 stators, are made at the same level. With this arrangement, even regarding the drive of a unit component as the X moment structure or Y movement structure, a moment about its gravity center is not at all produced. Consequently, excitation of vibration to the stage base 4 can be avoided
20 effectively.

 Although the present embodiment has been described with reference to an example wherein the Y beam comprises two, upper and lower beams, while the X beam comprises a single beam,
25 in reverse the X beam may comprise two, upper and lower beams and the Y beam may comprise a single beam. Substantially the same advantageous effects

are obtainable in that occasion. Further, the number of beams is not limited to two, and three or more beams may be used. Also, the other beam is not limited to a single beam, such that plural
5 beams may be used for both of the X and Y beams. One of the X and Y beams may comprise beams of an even number, while the other may comprise beams of an odd number, for example, a combination of two beams and three beams in different directions.

10

[Forth embodiment: Exposure Apparatus]

Figure 8 is a schematic view of a general structure of an exposure apparatus in which a positioning system such as described above
15 is incorporated as a substrate stage system and/or an original stage system. In this exposure apparatus, an original (reticle or mask) 521 held by an original stage 520 is illuminated by an illumination optical system 510, and a pattern of
20 the original 521 is projected by a projection optical system 530 onto a substrate (wafer) 541 placed on a substrate stage (wafer stage) 540, whereby the substrate 541 is exposed with the pattern. Here, each of the stages 520 and 540
25 comprises a positioning system as has been described with reference to any one of the first to third embodiments.

In accordance with the exposure apparatus having a positioning system according to any one of the preceding embodiments, a drive reaction force to be produced during acceleration or deceleration of the movable table can be converted into kinetic energies through the motion of the motor stators in an opposite direction and it can be absorbed thereby. Simultaneously, with the structure in which the gravity center positions of various movement components are held approximately at the same level, vibration to be applied to the stage base due to the moment reaction force can be cancelled effectively. As a result, unwanted swinging motion or vibration of the base table attributable to the drive reaction force or moment can be reduced and suppressed, such that high-speed and high-precision positioning can be accomplished. Hence, with use of such high-speed and high-precision positioning system the throughput of the exposure apparatus can be improved significantly.

[Fifth Embodiment: Semiconductor Device Manufacturing Processes]

Next, an embodiment of a semiconductor device manufacturing method which uses an exposure apparatus described above, will be explained.

Figure 6 is a flow chart for explaining general procedure for manufacturing various microdevices such as semiconductor devices, for example. Step 1 is a design process for designing a circuit of a semiconductor device. Step 2 is a process for making a mask on the basis of the circuit pattern design. Step 3 is a process for preparing a wafer by using a material such as silicon. Step 4 is a wafer process which is called a pre-process wherein, by using the thus prepared mask and wafer, a circuit is formed on the wafer in practice, in accordance with lithography. Step 5 subsequent to this is an assembling step which is called a post-process wherein the wafer having been processed at step 4 is formed into semiconductor chips. This step includes an assembling (dicing and bonding) process and a packaging (chip sealing) process. Step 6 is an inspection step wherein an operation check, a durability check and so on, for the semiconductor devices produced by step 5, are carried out. With these processes, semiconductor devices are produced, and they are shipped (step 7).

Figure 7 is a flow chart for explaining details of the wafer process. Step 11 is an oxidation process for oxidizing the surface of a

wafer. Step 12 is a CVD process for forming an insulating film on the wafer surface. Step 13 is an electrode forming process for forming electrodes upon the wafer by vapor deposition.

5 Step 14 is an ion implanting process for implanting ions to the wafer. Step 15 is a resist process for applying a resist (photosensitive material) to the wafer. Step 16 is an exposure process for printing, by exposure, the circuit
10 pattern of the mask on the wafer through the exposure apparatus described above. Step 17 is a developing process for developing the exposed wafer. Step 18 is an etching process for removing portions other than the developed resist image.

15 Step 19 is a resist separation process for separating the resist material remaining on the wafer after being subjected to the etching process. By repeating these processes, circuit patterns are superposedly formed on the wafer.

20 With these processes, high density microdevices can be manufactured.

While the invention has been described with reference to the structures disclosed herein, it is not confined to the details set forth and
25 this application is intended to cover such modifications or changes as may come within the purposes of the improvements or the scope of the

following claims.
